

## AP<sup>®</sup> Statistics 2002 Sample Student Responses

**The materials included in these files are intended for use by AP teachers for course and exam preparation in the classroom; permission for any other use must be sought from the Advanced Placement Program<sup>®</sup>. Teachers may reproduce them, in whole or in part, in limited quantities, for face-to-face teaching purposes but may not mass distribute the materials, electronically or otherwise. These materials and any copies made of them may not be resold, and the copyright notices must be retained as they appear here. This permission does not apply to any third-party copyrights contained herein.**

These materials were produced by Educational Testing Service<sup>®</sup> (ETS<sup>®</sup>), which develops and administers the examinations of the Advanced Placement Program for the College Board. The College Board and Educational Testing Service (ETS) are dedicated to the principle of equal opportunity, and their programs, services, and employment policies are guided by that principle.

The College Board is a national nonprofit membership association dedicated to preparing, inspiring, and connecting students to college and opportunity. Founded in 1900, the association is composed of more than 4,200 schools, colleges, universities, and other educational organizations. Each year, the College Board serves over three million students and their parents, 22,000 high schools, and 3,500 colleges, through major programs and services in college admission, guidance, assessment, financial aid, enrollment, and teaching and learning. Among its best-known programs are the SAT<sup>®</sup>, the PSAT/NMSQT<sup>®</sup>, and the Advanced Placement Program<sup>®</sup> (AP<sup>®</sup>). The College Board is committed to the principles of equity and excellence, and that commitment is embodied in all of its programs, services, activities, and concerns.

5. Sleep researchers know that some people are early birds (E), preferring to go to bed by 10 P.M. and arise by 7 A.M., while others are night owls (N), preferring to go to bed after 11 P.M. and arise after 8 A.M. A study was done to compare dream recall for early birds and night owls. One hundred people of each of the two types were selected at random and asked to record their dreams for one week. Some of the results are presented below.

Group	Number of Dreams Recalled During the Week			Proportion Who Recalled	
	Mean	Median	Standard Deviation	No dreams	5 or more dreams
Early birds	7.26	6.0	6.94	0.24	0.55
Night owls	9.55	9.5	5.88	0.11	0.69

- (a) The researchers believe that night owls may have better dream recall than do early birds. One parameter of interest to the researchers is the mean number of dreams recalled per week with  $\mu_E$  representing this mean for early birds and  $\mu_N$  representing this mean for night owls. The appropriate hypotheses would then be  $H_0: \mu_E - \mu_N = 0$  and  $H_a: \mu_E - \mu_N < 0$ . State two other pairs of hypotheses that might be used to test the researchers' belief. Be sure to define the parameter of interest in each case.

$H_0: p_E - p_N = 0$  (where the proportion of early birds who remembered no dreams equals the proportion of night owls who remembered no dreams)

$H_a: p_E - p_N > 0$  (where the proportion of early birds who remembered no dreams is greater than the proportion of night owls who remembered no dreams)

$H_0: p_E - p_N = 0$  (where the proportion of early birds who remembered 5 or more dreams equals the proportion of night owls who remembered 5 or more dreams)

$H_a: p_E - p_N < 0$  (where the proportion of early birds who remembered 5 or more dreams is less than the proportion of night birds who remembered 5 or more dreams)

- (b) Use the data provided to carry out a test of the hypotheses about the mean number of dreams recalled per week given in the statement of part (a). Do the data support the researchers' belief?

A two-sample difference of means  $t$ -test is appropriate for this data. We can safely use this test because the two samples are independent, the samples are random samples, the population standard deviations are unknown, and both sample sizes are greater than 30.

$H_0: \mu_E - \mu_N = 0$  (where the mean number of dreams remembered by early birds equals the mean number of dreams remembered by night owls)

$H_a: \mu_E - \mu_N < 0$  (where the mean number of dreams remembered by early birds is less than the mean number of dreams remembered by night owls).

$$\bar{x}_E = 7.26 \quad s_E = 6.94 \quad \bar{x}_N = 9.55 \quad s_N = 5.88 \quad df = 192.799 \text{ (from calculator)}$$

$$\begin{aligned} P(\bar{x}_E - \bar{x}_N < 7.26 - 9.55) &= P\left(t < \frac{(\bar{x}_E - \bar{x}_N) - 0}{\sqrt{\frac{s_E^2}{n_E} + \frac{s_N^2}{n_N}}}\right) \\ &= P\left(t < \frac{(7.26 - 9.55) - 0}{\sqrt{\frac{(6.94)^2}{100} + \frac{(5.88)^2}{100}}}\right) = P(t < -2.5176) = .006315 \end{aligned}$$

If the null hypothesis is true, the probability of obtaining two sample means with a difference (early birds - night owls) of less than  $-2.29$  is  $.006315$ . We have very strong evidence against the null hypothesis and in support of the researchers' belief that night owls have better recall than early birds.

5. Sleep researchers know that some people are early birds (E), preferring to go to bed by 10 P.M. and arise by 7 A.M., while others are night owls (N), preferring to go to bed after 11 P.M. and arise after 8 A.M. A study was done to compare dream recall for early birds and night owls. One hundred people of each of the two types were selected at random and asked to record their dreams for one week. Some of the results are presented below.

Group	Number of Dreams Recalled During the Week			Proportion Who Recalled	
	Mean	Median	Standard Deviation	No dreams	5 or more dreams
Early birds	7.26	6.0	6.94	0.24	0.55
Night owls	9.55	9.5	5.88	0.11	0.69

(a) The researchers believe that night owls may have better dream recall than do early birds. One parameter of interest to the researchers is the mean number of dreams recalled per week with  $\mu_E$  representing this mean for early birds and  $\mu_N$  representing this mean for night owls. The appropriate hypotheses would then be  $H_0: \mu_E - \mu_N = 0$  and  $H_a: \mu_E - \mu_N < 0$ . State two other pairs of hypotheses that might be used to test the researchers' belief. Be sure to define the parameter of interest in each case.

$$H_0: M_E - M_N = 0$$

$$H_A: M_E - M_N < 0$$

This hypothesis <sup>compares</sup> the median number of dreams recalled during the week with  $M_E$  representing the median for early birds and  $M_N$  representing the median for night owls.

$$H_0: P_E - P_N = 0$$

$$H_A: P_E - P_N < 0$$

This hypothesis compares the proportion who recalled 5 or more dreams during the week with  $P_E$  representing the proportion of early birds and  $P_N$  being that of the night owls.

(b) Use the data provided to carry out a test of the hypotheses about the mean number of dreams recalled per week given in the statement of part (a). Do the data support the researchers' belief?

$$H_0: \mu_E - \mu_N = 0$$

$$H_A: \mu_E - \mu_N < 0$$

The difference in the mean number of dreams of early birds ( $\mu_E$ ) and night owls ( $\mu_N$ ) is equal to zero or (is) than zero.

- assumptions:
- 1) The samples are random for all early birds and night owls.
  - 2) The standard deviation of the populations are unknown.
  - 3) The distribution is assumed to be normal.

Therefore, I will use  $t$ -procedures for differences in population means with 99 (20) degrees of freedom.

$$\begin{aligned} \text{test statistic} &= \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{\sqrt{\frac{s_1^2}{n_1} + \frac{s_2^2}{n_2}}} \\ &= \frac{(9.55 - 7.26) - 0}{\sqrt{\frac{5.882}{100} + \frac{6.94^2}{100}}} \\ &= \frac{2.29}{.358} = 2.518 \end{aligned}$$

Initial decision - reject  $H_0$ .

Final conclusion - There is sufficient evidence to indicate that the difference in mean number of dreams recalled during the week of early birds and night owls is less than zero. That is, night owls recall more dreams per week on average than do early birds. The p-value at  $t = 2.518$  of .0063 supports this conclusion since if  $H_0$  were true, we would observe results this extreme only .63% of the time.

• Therefore, the data does support the researchers belief that night owls have better dream recall than do early birds.
